

Push_swap

Because Swap_push isn't as natural

Summary:

This project will make you sort data on a stack, with a limited set of instructions, using the lowest possible number of actions. To succeed you'll have to manipulate various types of algorithms and choose the most appropriate solution (out of many) for an optimized data sorting.

Version: 7

Chapter I

Foreword

- C

```
#include <stdio.h>

int main(void)
{
    printf("hello, world\n");
    return 0;
}
```

- ASM

```
cseg segment
assume cs:cseg, ds:cseg
org 100h
main proc
jmp debut
mess db 'Hello world!$'
debut:
mov dx, offset mess
mov ah, 9
int 21h
ret
main endp
cseg ends
end main
```

- LOLCODE

```
HAI
CAN HAS STDIO?
VISIBLE "HELLO WORLD!"
KTHXBYE
```

- PHP

```
<?php
echo "Hello world!";
?>
```

- BrainFuck

```
++++++++++[>++++++>++++++>+++>+<<<-]
>++.>.++++++.+++.>+.
<<+++++++.>.+++.-----.-----.>+.>.
```

Push_swap

Because Swap_push isn't as natural

- C#

```
using System;

public class HelloWorld {
    public static void Main () {
        Console.WriteLine("Hello world!");
    }
}
```

- HTML5

```
<!DOCTYPE html>
<html>
    <head>
        <meta charset="utf-8">
        <title>Hello world !</title>
    </head>
    <body>
        <p>Hello World !</p>
    </body>
</html>
```

- YASL

```
"Hello world!"
print
```

- OCaml

```
let main () =
    print_endline "Hello world !"

let _ = main ()
```

V.2 Example

To illustrate the effect of some of these instructions, let's sort a random list of integers. In this example, we'll consider that both stacks grow from the right.

```
Init a and b:
```

```
2  
1  
3  
6  
5  
8  
--  
a b
```

```
Exec sa:
```

```
1  
2  
3  
6  
5  
8  
--  
a b
```

```
Exec pb pb pb:
```

```
6 3  
5 2  
8 1  
--  
a b
```

```
Exec ra rb (equiv. to rr):
```

```
5 2  
8 1  
6 3  
--  
a b
```

```
Exec rra rrb (equiv. to rrr):
```

```
6 3  
5 2  
8 1  
--  
a b
```

```
Exec sa:
```

```
5 3  
6 2  
8 1  
--  
a b
```

```
Exec pa pa pa:
```

```
1  
2  
3  
5  
6  
8  
--  
a b
```

Integers from a get sorted in 12 instructions. Can you do better?

```
$>./push_swap 2 1 3 6 5 8
sa
pb
pb
pb
sa
pa
pa
pa
$>./push_swap 0 one 2 3
Error
$>
```

During the evaluation process, a binary will be provided in order to properly check your program.

It will work as follows:

```
$>ARG="4 67 3 87 23"; ./push_swap $ARG | wc -l
      6
$>ARG="4 67 3 87 23"; ./push_swap $ARG | ./checker_OS $ARG
OK
$>
```

If the program `checker_OS` displays "KO", it means that your `push_swap` came up with a list of instructions that doesn't sort the numbers.

The `checker_OS` program is available in the resources of the project in the intranet.
You can find a description of how it works in the Bonus Part of this document.

Chapter VI

Bonus part

This project leaves little room for adding extra features due to its simplicity. However, how about creating your own checker?

Thanks to the checker program, you will be able to check whether the list of instructions generated by the push_swap program actually sorts the stack properly.

VI.1 The "checker" program

Program name	checker
Turn in files	*.h, *.c
Makefile	bonus
Arguments	stack a: A list of integers
External functs.	<ul style="list-style-type: none">• read, write, malloc, free, exit• ft_printf and any equivalent YOU coded
Libft authorized	Yes
Description	Execute the sorting instructions

- Write a program named `checker` that takes as an argument the stack `a` formatted as a list of integers. The first argument should be at the top of the stack (be careful about the order). If no argument is given, it stops and displays nothing.
- It will then wait and read instructions on the standard input, each instruction will be followed by '\n'. Once all the instructions have been read, the program has to execute them on the stack received as an argument.

- If after executing those instructions, the stack **a** is actually sorted and the stack **b** is empty, then the program must display "OK" followed by a '\n' on the standard output.
- In every other case, it must display "KO" followed by a '\n' on the standard output.
- In case of error, you must display "Error" followed by a '\n' on the **standard error**. Errors include for example: some arguments are not integers, some arguments are bigger than an integer, there are duplicates, an instruction doesn't exist and/or is incorrectly formatted.

```
$>./checker 3 2 1 0
rra
pb
sa
rra
pa
OK
$>./checker 3 2 1 0
sa
rra
pb
KO
$>./checker 3 2 one 0
Error
$>./checker "" 1
Error
$>
```

You DO NOT have to reproduce the exact same behavior as the provided binary. It is mandatory to manage errors but it is up to you to decide how you want to parse the arguments.

The bonus part will only be assessed if the mandatory part is **PERFECT**. Perfect means the mandatory part has been integrally done and works without malfunctioning. If you have not passed **ALL** the mandatory requirements, your bonus part will not be evaluated at all.
